

SAFU: a deterministic loss-socialization protocol. Built for protocols, wallet providers, and platforms holding user funds.

Businesses deploy a SAFU-powered pool. A verified drain pays out automatically, no vote, no discretionary review.

Grant Application, 2026

**A wallet drain has no deterministic recovery path today.
Ours took two months and a police report, and there were
207 separate security incidents in H1 2026, totaling \$972M.**

SAFU's founder started building in January 2026, while that recovery was still underway, because a decentralized industry shouldn't route recovery through a centralized, discretionary process that slow.

Source: Binance Research, H1 2026

That two-month recovery followed a wallet compromise on December 24, 2025: identity verification, then a police report.

A business deploys a SAFU-powered pool, funded by its own seed capital together with its end-users staking on top. A verified drain triggers an automatic payout, up to a fixed multiple of the stake, sized to the wallet's risk tier and never more than the loss. It covers individuals, autonomous agents, and protocols alike.

✓ No human vote

✓ No manual override

✓ Deterministic payout

SAFUPoolV8.sol is Etherscan-verified and live on Ethereum mainnet, backed by 75/75 EVM tests, 184/184 Soroban tests, and Halmos symbolic verification at 10/10 properties with zero counterexamples.

Whitelabel Pools serve two use cases: retail, live now, and protocol, detection built, pool not yet launched.

	WHITELABEL POOLS (RETAIL)	WHITELABEL POOLS (PROTOCOL)
Launched by	A protocol, wallet provider, platform, or ecosystem	An ecosystem only
Funded by	The launcher's own seed capital, together with end-users staking on top	Optional seed capital from the ecosystem, together with member protocols staking into the pool
Who's covered	The protocol's retail end-users, individuals and autonomous agents alike	The protocol itself, so its users never feel the loss
Hacks covered	Phishing, approval exploits, key compromise, MEV sandwich attacks	Oracle manipulation, governance manipulation, privileged-function abuse, cross-chain mismatches
Status	Live today on SAFUPoolV8, Ethereum mainnet	Detection built, pool not yet launched

Three deterministic steps turn a drain event into a payout, and every replay of the same inputs produces the same output.

Every alternative is bought with a premium or a subscription, and five of six settle by a human decision. SAFU is funded by the staker's own stake, and the contract pays automatically as soon as a drain is verified.

PROTOCOL	WHO DECIDES A CLAIM	WHAT TRIGGERS PAYOUT	WALLET DRAINS
Nexus Mutual	Claims Committee, 2 of 3	Discretionary	Platform only
InsurAce	Advisory board, then token vote	Assessed	No
Unslashed Finance	Capital-provider model	Assessed	No
Risk Harbor (now Subsea)	Automated, no assessor	Parametric, yield and stablecoin	No
Fairside	Assessors, then DAO vote	Assessed, annual premium	Yes
MetaMask Transaction Shield	MetaMask reviews	Pre-approved transactions, subscription	Excluded
SAFU	The contract	Verified drain, up to a fixed multiple of the stake, capped at the loss	Yes

Capital has left these models: Nexus Mutual from about \$780M at its 2021 peak to roughly \$86M, InsurAce to about \$134K, Unslashed to \$2.8M, Risk Harbor to \$38K. Pool capital, DefiLlama, August 2026. SAFU's pools are funded by the people being covered.

Pre-revenue today. Revenue follows the grant-deployment sequence: grants build credibility, credibility opens whitelabel sales.

REVENUE LINE	FUNDED BY	TIMELINE
Grants, spent on SAFU's own dev and audit costs	SCF #44 (\$30K) + Areta (\$2K), non-dilutive	Now, in hand
Whitelabel pool fees, retail and protocol variants, a fixed fee or a percentage of the pool per partner	Protocol/ecosystem seed capital plus end-user staking (retail), or member protocols plus optional ecosystem seed capital (protocol)	Near-term, once first pilot signs

Model 2, direct consumer pools: individuals and autonomous agents stake directly into SAFU's own pool for personal coverage. Launches once Model 1 produces real traction.

Model 3, SAFU Audit: a protocol deposits capital into a coverage pool instead of paying a traditional audit fee, and SAFU's team reviews the code and sets coverage from that review. Launches once Model 1 has traction.

Live and adversarially tested on Ethereum mainnet today, backed by two independent third-party awards.

A chain that integrates SAFU keeps more value on it.

A drain stops being a total loss, so holders and protocols are willing to keep more value on that chain and move it through the applications built there, without the chain itself having to build the coverage layer. A chain can stand up a pool together with SAFU, and a protocol on that chain can deploy its own pool with SAFU's detection built into it. When an exploit hits, the payout goes to the protocol itself, fast enough to stop a bank run before it starts, so its users never see a locked balance.

SAFU's SCF #44 application worked through the Blend and YieldBlox exploit on Stellar, where a single trade moved USTRY from \$1 to \$106 and the attacker borrowed 61 million XLM against their own inflated collateral, the pattern SAFU's oracle-manipulation detection fires on.

Ethereum

● live now

Stellar

● testnet, SCF #44-funded

Pool deployment on any further chain follows once that chain's own grant lands, evaluated case by case.

Two founders, building together since January 2026.

Murtaza Kanchwala

Co-founder & Protocol Lead

Leads architecture, smart contracts, and technical execution. Twelve years across Web3, international trade, retail, and construction, including one year hands-on and a Data Science (R) certificate, Harvard Online, 2021. Built the Solidity pool contracts and Python Detection Engine end-to-end, live on Ethereum mainnet.

Deniz Köse

Co-founder, BD & Marketing

Leads partnerships and go-to-market. Industrial Engineering, Koç University; six years across energy, international trading, and crypto.

Asking \$200,000 to fund five sequenced milestones

- | | |
|----|--|
| 01 | Whitelabel deployment package productized, reusing the contracts and backend already live on Ethereum · \$60K |
| 02 | Contracts hardened and grant-funded security audit complete, the credibility milestone that unlocks protocol outreach on the funding chain · \$35K |
| 03 | Whitelabel pool deployed and tested on the funding chain · \$45K |
| 04 | First signed whitelabel partner live on that pool · \$45K |
| 05 | Case study published on the first live deployment · \$15K |

Engineering \$160K · infrastructure \$25K · audit \$15K

Longer term, once Model 1 produces real traction: a dedicated push into direct consumer reach for the same pool individuals and autonomous agents can already stake into today, and letting a protocol deposit capital into a coverage pool instead of paying a traditional audit fee, reviewed and priced by SAFU's own team.

Two ecosystem grant programs already fund this model: Stellar Community Fund #44 (\$30,000) and the Areta Ethereum Audit Subsidy (\$2,000), \$32,000 awarded to date.
