

Protocols, wallet providers, and platforms holding user funds deploy a SAFU-powered pool for their own users, individuals or autonomous agents alike, and a verified wallet drain pays out **automatically, up to a fixed multiple of the stake and never more than the loss.**

BUILT FOR

Ecosystems Protect the protocols built on you. When one is hacked, the payout goes to the protocol itself, fast enough to stop a bank run before it starts.	Protocols Protect the people using your contracts, whether they manage funds by hand or through an autonomous agent.
Wallet providers Offer real cover inside your own wallet product.	Platforms holding user funds Give the users whose funds you already hold a payout path if their wallet is drained, funded by their own stake.

THE PROBLEM

A drained wallet has no deterministic recovery path. When a wallet was compromised on December 24, 2025, recovering funds meant proving identity and filing a police report, and that process ran close to two months. There were **207 separate security incidents** in the first half of 2026, totaling \$972 million.

HOW IT WORKS: RETAIL POOL

01 A protocol, wallet provider, or platform deploys a pool for its users.	02 Users, individuals or autonomous agents, stake assets into that pool.	03 SAFU's detection engine verifies a drain on chain.	04 The contract pays the drained wallet, up to a fixed multiple of its stake, sized to its risk tier, and never more than the loss.
---	--	---	---

HOW IT WORKS: PROTOCOL POOL

01 An ecosystem deploys a pool that member protocols stake into, with optional seed capital from the ecosystem.	02 A protocol within that ecosystem is hacked.	03 SAFU's detection engine verifies the exploit on chain.	04 The contract pays the protocol directly, fast enough to stop a bank run before it starts.
---	--	---	--

Neither flow has a vote or a claim form. The contract enforces the payout rule itself.

ALREADY RUNNING

- ✓ SAFUPoolV8 live on Ethereum mainnet, source verified and published.
- ✓ Symbolically verified with Halmos, zero counterexamples.
- ✓ Soroban contract on Stellar testnet, 184 of 184 tests passing.
- ✓ Deterministic by design, so replays match exactly.

WHITELABEL POOLS

The same contracts and detection engine deploy under a partner's own name. A protocol, wallet provider, or platform runs its own pool, seeds it alongside its users, and protects those users directly without building a coverage layer in house. An ecosystem can deploy the same technology one level up: member protocols stake into a shared pool, with optional seed capital from the ecosystem, that protects them instead of end-users directly. Each partner pool runs the same verification and the same payout rule as the pool already live on Ethereum. A chain that integrates SAFU keeps more value on it: a drain stops being a total loss, so holders and protocols are willing to keep more value there and move it through the applications built on that chain.

TEAM AND FUNDING

Two founders have been building SAFU since January 2026, based in Istanbul, Turkey, operating as MKD Global LLC. Funding to date is non-dilutive: **\$30,000** from the Stellar Community Fund under SCF #44, and a **\$2,000** Ethereum audit subsidy from Areta. No equity or token round has been raised.

GRANT ASK

MILESTONE	AMOUNT
1. Whitelabel deployment package productized	\$60,000
2. Contracts hardened and grant-funded security audit complete	\$35,000
3. Whitelabel pool deployed and tested on the funding chain	\$45,000
4. First signed whitelabel partner live on that pool	\$45,000
5. Case study published on the first live deployment	\$15,000
Total	\$200,000
Engineering \$110K · coverage and outreach \$50K · infrastructure \$25K · audit \$15K. \$60,000 completes milestone 1, \$200,000 covers all five.
